A UNIFORM MODEL FOR KIRILLOV–RESHETIKHIN CRYSTALS
EXTENDED ABSTRACT

CRISTIAN LENART, SATOSHI NAITO, DAISUKE SAGAKI, ANNE SCHILLING, AND MARK SHIMOZONO

Abstract. We present a uniform construction of tensor products of one-column Kirillov–Reshetikhin (KR) crystals in all untwisted affine types, which uses a generalization of the Lakshmibai–Seshadri paths (in the theory of the Littelmann path model). This generalization is based on the graph on parabolic cosets of a Weyl group known as the parabolic quantum Bruhat graph. A related model is the so-called quantum alcove model. The proof is based on two lifts of the parabolic quantum Bruhat graph: to the Bruhat order on the affine Weyl group and to Littelmann’s poset on level-zero weights. Our construction leads to a simple calculation of the energy function. It also implies the equality between a Macdonald polynomial specialized at \( t = 0 \) and the graded character of a tensor product of KR modules.

1. Introduction

Our goal in this series of papers (see [LNSSS1, LNSSS2]) is to obtain a uniform construction of tensor products of one-column Kirillov–Reshetikhin (KR) crystals. As a consequence we shall prove the equality \( P_\lambda(q) = X_\lambda(q) \), where \( P_\lambda(q) \) is the Macdonald polynomial \( P_\lambda(q, t) \) specialized at \( t = 0 \) and \( X_\lambda(q) \) is the graded character of a simple Lie algebra coming from tensor products of KR modules. Both the Macdonald polynomials and KR modules are of arbitrary untwisted affine type. The index \( \lambda \) is a dominant weight for the simple Lie subalgebra coming from tensor products of KR modules. Our results apply to the untwisted affine root systems. The overlapping cases are the simply-laced affine root systems \( A^{(1)}_n \), \( D^{(1)}_n \), and \( E^{(1)}_6, 7, 8 \).

It is known [FL, FSS, KMOU, KMOTU, ST, Na] that certain affine Demazure characters (including those for the simply-laced affine root systems) can be expressed in terms of KR crystals, which motivates the relation between \( P \) and \( X \). For types \( A^{(1)}_n \) and \( C^{(1)}_n \), the equality \( P = X \) was achieved in [Le2, LeS] by establishing a combinatorial formula for the Macdonald polynomials at \( t = 0 \) from the Ram–Yip formula [RY], and by using explicit models for the one-column KR crystals [FOS]. It should be noted that, in types \( A^{(1)}_n \) and \( C^{(1)}_n \), the one-column KR modules are irreducible when restricted to the canonical simple Lie subalgebra, while in general this is not the case. For the cases considered by Ion [Ion], the corresponding KR crystals are perfect. This is not necessarily true for the untwisted affine root systems considered in this work, especially for the untwisted non-simply-laced affine root systems.

Key words and phrases. Parabolic quantum Bruhat graph, Kirillov–Reshetikhin crystals, energy function, Lakshmibai–Seshadri paths, Macdonald polynomials.
In this work we provide a type-free approach to the equality $P = X$ for untwisted affine root systems. Lenart’s specialization [Le2] of the Ram–Yip formula for Macdonald polynomials uses the quantum alcove model [LeL1], whose objects are paths in the quantum Bruhat graph (QBG), which was defined and studied in [BFP] in relation to the quantum cohomology of the flag variety. On the other hand, Naito and Sagaki [NS1, NS2, NS4, NS5] gave models for tensor products of KR crystals of one-column type in terms of projections of level-zero Lakshmibai–Seshadri (LS) paths to the classical weight lattice. Hence we need to establish a bijection between the quantum alcove model and projected level-zero LS paths.

In analogy with [BFP] and inspired by the quantum Schubert calculus of homogeneous spaces [Mi, P] we define the parabolic quantum Bruhat graph (PQBG), which is a directed graph structure on parabolic quotients of the Weyl group with respect to a parabolic subgroup. We construct two lifts of the PQBG. The first lift is from the PQBG to the Bruhat order of the affine Weyl group. This is a parabolic analogue of the lift of the QBG to the affine Bruhat order [LS], which is the combinatorial structure underlying Peterson’s theorem [P]; the latter equates the Gromov-Witten invariants of finite-dimensional homogeneous spaces with the Pontryagin homology structure constants of Schubert varieties in the affine Grassmannian. We obtain Diamond Lemmas for the PQBG via projection of the standard Diamond Lemmas for the affine Weyl group. We find a second lift of the PQBG into a poset of Littelmann [Li] for level-zero weights and characterize its local structure (such as cover relations) in terms of the PQBG. Littelmann’s poset was defined in connection with LS paths for arbitrary (not necessarily dominant) weights, but the local structure was not previously known. The weight poset precisely controls the combinatorics of the level-zero LS paths and therefore their classical projections, which we formulate directly as quantum LS paths. Finally, we describe a bijection between the quantum alcove model and the quantum LS paths.

The paper is organized as follows. In Section 2 we prepare the background and define the PQBG. Section 3 is reserved for the two lifts of the PQBG and the statement of the Diamond Lemmas. In Section 4 we describe KR crystals in terms of the quantum LS paths and the quantum alcove model in [LeL1]; we also give simple combinatorial formulas for the energy function. Finally, we conclude in Section 5 with the results on (nonsymmetric) Macdonald polynomials at $t = 0$.

Acknowledgments. The first two and last two authors would like to thank the Mathematisches Forschungsinstitut Oberwolfach for their support during the Research in Pairs program, where some of the main ideas of this paper were conceived. We would also like to thank Thomas Lam for helpful discussions during FPSAC12 in Nagoya, Japan and Daniel Orr for his discussions about Ion’s work [Ion]. We used SAGE [Sa] and SAGE-COMBINAT [Sa-comb] to discover properties about the level-zero weight poset and to obtain some of the pictures in this paper.

2. Background

2.1. Untwisted affine root datum. Let $I = I \cup \{0\}$ (resp. $I$) be the Dynkin node set of an untwisted affine algebra $\mathfrak{g}_{af}$ (resp. its canonical subalgebra $\mathfrak{g}$), $W_{af}$ (resp. $W$) the affine (resp. finite) Weyl group with simple reflections $r_i$ for $i \in I_{af}$ (resp. $i \in I$), and $X_{af} = \mathbb{Z} \delta \oplus \bigoplus_{i \in I_{af}} \mathbb{Z} \alpha_i$ (resp. $X = \bigoplus_{i \in I} \mathbb{Z} \omega_i$) the affine (resp. finite) weight lattice. Let $\{ \alpha_i | i \in I_{af} \}$ be the simple roots, $\Phi_{af} = W_{af}\{ \alpha_i | i \in I_{af} \}$ (resp. $\Phi = W\{ \alpha_i | i \in I \}$) the set of affine real roots (resp. roots), and $\Phi_{af}^{\pm} = \Phi_{af} \cap \bigoplus_{i \in I_{af}} \mathbb{Z}_{\geq 0} \alpha_i$ (resp. $\Phi^{\pm} = \Phi \cap \bigoplus_{i \in I} \mathbb{Z}_{\geq 0} \alpha_i$) the set of positive affine real (resp. positive) roots. Furthermore, $\Phi_{af}^{-} = -\Phi_{af}^{+}$ (resp. $\Phi^{-} = -\Phi^{+}$) are the negative affine real (resp. negative) roots. Let $X_{af}^\vee = \text{Hom}_{\mathbb{Z}}(X_{af}, \mathbb{Z})$ be the dual lattice, $\langle \cdot, \cdot \rangle : X_{af}^\vee \times X_{af} \rightarrow \mathbb{Z}$ the evaluation.
pairing, and \( \{d\} \cup \{\alpha_i^\vee \mid i \in I_{af}\} \) the dual basis of \( X_{af}^\vee \). The natural projection \( \text{cl} : X_{af} \to X \) has kernel \( \mathbb{Z} \Lambda_0 \oplus \mathbb{Z} \delta \) and sends \( \Lambda_i \mapsto \omega_i \) for \( i \in I \).

The affine Weyl group \( W_{af} \) acts on \( X_{af} \) and \( X_{af}^\vee \) by

\[
  r_i \lambda = \lambda - \langle \alpha_i^\vee, \lambda \rangle \alpha_i \quad \text{and} \quad r_i \mu = \mu - \langle \mu, \alpha_i \rangle \alpha_i^\vee,
\]

for \( i \in I_{af}, \lambda \in X_{af}, \) and \( \mu \in X_{af}^\vee \). For \( \beta \in \Phi_{af} \), let \( w \in W_{af} \) and \( i \in I_{af} \) be such that \( \beta = w \alpha_i \).

Define the associated reflection \( r_\beta \in W_{af} \) and associated coroot \( \beta^\vee \in X_{af}^\vee \) by \( r_\beta = wr_iw^{-1} \) and \( \beta^\vee = w \alpha_i^\vee \).

The null root is the unique element \( \delta = \bigoplus_{i \in I_{af}} \mathbb{Z}_{>0} \alpha_i \) which generates the rank 1 sublattice \( \{ \lambda \in X_{af} \mid \langle \alpha_i^\vee, \lambda \rangle = 0 \text{ for all } i \in I_{af} \} \). We have \( \delta = \alpha_0 + \theta \), where \( \theta \) is the highest root for \( g \).

The canonical central element is the unique element \( c = \bigoplus_{i \in I_{af}} \mathbb{Z}_{>0} \alpha_i^\vee \) which generates the rank 1 sublattice \( \{ \mu \in X_{af}^\vee \mid \langle \mu, \alpha_i \rangle = 0 \text{ for all } i \in I_{af} \} \). The level of a weight \( \lambda \in X_{af} \) is defined by \( \text{level}(\lambda) = \langle c, \lambda \rangle \).

Let \( X_{af}^0 \subset X_{af} \) be the sublattice of level-zero elements.

We denote by \( \ell(w) \) for \( w \in W_{af} \) (resp. \( W \)) the length of \( w \) and by \( \ll \) the Bruhat cover. The element \( t_\mu \in W_{af} \) is the translation by the element \( \mu \) in the coroot lattice \( Q^\vee = \bigoplus_{i \in I} \mathbb{Z} \alpha_i^\vee \).

2.2. Affinization of a weight stabilizer. Let \( \lambda \in X \) be a dominant weight, which is fixed throughout the remainder of Sections 2 and 3. Let \( W_J \) be the stabilizer of \( \lambda \in W \). It is a parabolic subgroup, being generated by \( r_i \) for \( i \in J \), where \( J = \{ i \in I \mid \langle \alpha_i^\vee, \lambda \rangle = 0 \} \). Let \( Q^\vee_J = \bigoplus_{i \in J} \mathbb{Z} \alpha_i^\vee \) be the associated coroot lattice, \( W^J \) the set of minimum-length coset representatives in \( W/W_J \), \( \Phi_J \supset \Phi_J^+ \) the set of roots and positive roots respectively, and \( \rho_J = (1/2) \sum_{\alpha \in \Phi_J^+} \alpha \) (if \( J = \emptyset \), then \( \rho_J \) is denoted by \( \rho \)).

Define

\[
  (W_J)_{af} = W_J \times Q^\vee_J = \{ wt_\mu \in W_{af} \mid w \in W_J, \mu \in Q^\vee_J \},
\]

\[
  \Phi^J_{af} = \{ \beta \in \Phi_{af}^+ \mid \text{cl}(\beta) \in \Phi_J \} = \Phi^+_J \cup (\mathbb{Z}_{>0} \delta + \Phi_J),
\]

\[
  (W^J)_{af} = \{ x \in W_{af} \mid x \cdot \beta > 0 \text{ for all } \beta \in \Phi^J_{af} \}.
\]

By [LS, Lemma 10.5] [P], any \( w \in W_{af} \) factors uniquely as \( w = w_1w_2 \), where \( w_1 \in (W^J)_{af} \) and \( w_2 \in (W_J)_{af} \). Therefore, we can define \( \pi_J : W_{af} \to (W^J)_{af} \) by \( w \mapsto w_1 \). We say that \( \mu \in Q^\vee \) is \( J \)-adjusted if \( \pi_J(t_\mu) = z_\mu t_\mu \) with \( z_\mu \in W_J \). Say that \( \mu \in Q^\vee \) is \( J \)-superantidominant if \( \mu \) is antidominant (i.e., \( \langle \mu, \alpha \rangle \leq 0 \) for all \( \alpha \in \Phi^+ \)), and \( \langle \mu, \alpha \rangle < 0 \) for all \( \alpha \in \Phi^+ \setminus \Phi^+_J \).

2.3. The parabolic quantum Bruhat graph. The parabolic quantum Bruhat graph \( QB(W^J) \) is a directed graph with vertex set \( W^J \), whose directed edges have the form \( w \xrightarrow{\alpha} [wr_\alpha] \) for \( w \in W^J \) and \( \alpha \in \Phi^+ \setminus \Phi^+_J \). Here we denote by \( [v] \) the minimum-length representative in the coset \( eW_J \) for \( v \in W \). There are two kinds of edges:

1. (Bruhat edge) \( w \ll wr_\alpha \). (One may deduce that \( wr_\alpha \in W^J \).)
2. (Quantum edge) \( \ell([wr_\alpha]) = \ell(w) + 1 - \langle \alpha^\vee, 2\rho - 2\rho_J \rangle \).

If \( J = \emptyset \), then we recover the quantum Bruhat graph \( QB(W) \) defined in [BFP].

3. Two lifts of the parabolic quantum Bruhat graph

3.1. Lifting \( QB(W^J) \) to \( W_{af} \). We construct a parabolic analogue of the lift of \( QB(W) \) to \( W_{af} \) given in [LS].

Let \( \Omega^\infty_J \subset W_{af} \) be the subset of elements of the form \( w\pi_J(t_\mu) \) with \( w \in W^J \) and \( \mu \in Q^\vee \) \( J \)-superantidominant and \( J \)-adjusted. We have \( \Omega^\infty_J \subset (W^J)_{af} \cap W_{af} \), where \( W_{af} \) is the set of minimum-length coset representatives in \( W_{af}/W \). Impose the Bruhat covers in \( \Omega^\infty_J \) whenever the connecting root has classical part in \( \Phi \setminus \Phi_J \). Then \( \Omega^\infty_J \) is a subposet of the Bruhat poset \( W_{af} \).

**Proposition 3.1.** Every edge in \( QB(W^J) \) lifts to a downward Bruhat cover in \( \Omega^\infty_J \), and every cover in \( \Omega^\infty_J \) projects to an edge in \( QB(W^J) \). More precisely:
(1) For any edge \([wr_\alpha] \xleftarrow{\gamma} w\) in \(QB(W^J)\), and \(\mu \in Q^\vee\) that is \(J\)-superantidominant and \(J\)-adjusted with \(\pi_J(t_\mu) = zt_\mu\), there is a covering relation \(y < x \in \Omega^\infty_J\) where
\[
x = wzr_{\alpha}, \quad y = xrr_{\alpha}t_{\chi(\alpha)}zt_\mu, \quad \bar{\alpha} = z^{-1}\alpha + (\chi + \langle \mu, z^{-1}\alpha \rangle)\delta \in \Phi^{af-},
\]
and \(\chi\) is 0 or 1 according as the arrow in \(QB(W^J)\) is of Bruhat or quantum type respectively.

(2) Suppose \(y < x\) is an arbitrary covering relation in \(\Omega^\infty_J\). Then we can write \(x = wzr_{\alpha}\) with \(w \in W^J\), \(z = z_\mu \in W_J\), and \(\mu \in Q^\vee\) \(J\)-superantidominant and \(J\)-adjusted, as well as \(y = xrr_{\gamma}\) with \(\gamma = z^{-1}\alpha + n\delta \in \Phi^{af}, \alpha \in \Phi^+ \setminus \Phi^+_J\), and \(n \in \mathbb{Z}\). With the notation \(\chi := n - \langle \mu, z^{-1}\alpha \rangle\), we have
\[
\chi \in \{0, 1\}, \quad \gamma = z^{-1}\alpha + (\chi + \langle \mu, z^{-1}\alpha \rangle)\delta \in \Phi^{af};
\]
furthermore, there is an edge \(wr_\alpha z \xleftarrow{\gamma} wz\) in \(QB(W)\) and an edge \([wr_\alpha] \xleftarrow{\gamma} w\) in \(QB(W^J)\), where both edges are of Bruhat type if \(\chi = 0\) and of quantum type if \(\chi = 1\).

3.2. The Diamond Lemmas. In the following, a dotted (resp. plain) edge represents a quantum (resp. Bruhat) edge in \(QB(W^J)\), whereas a dashed edge can be of both types. Given \(w \in W^J\) and \(\gamma \in \Phi^+\), define \(z \in W_J\) by \(rw = r_{\gamma}wz\). We now state the Diamond Lemmas for \(QB(W^J)\). They are proved based on the lift of \(QB(W^J)\) to \(W_{af}\) in Proposition 3.1 and the fact that such a lemma holds for any Coxeter group [BB].

**Lemma 3.2.** Let \(\alpha \in \Phi\) be a simple root, \(\gamma \in \Phi^+ \setminus \Phi^+_J\), and \(w \in W^J\). Then we have the following cases, in each of which the bottom two edges imply the top two edges, and vice versa.

1. In the left diagram we assume \(\gamma \neq w^{-1}(\alpha)\). In both cases we have \(r_\alpha[wr_\gamma] = [r_\alpha wr_\gamma]\).

   \[
   \begin{array}{ccc}
   r_\alpha[w_{\gamma}] & \xleftarrow{\gamma} & [w_{\gamma}]^{-1}(\alpha) \\
   \downarrow \gamma & & \downarrow [w_{\gamma}]^{-1}(\alpha) \\
   r_\alpha[w] & \xleftarrow{\gamma} & [w]^{-1}(\alpha)
   \end{array}
   \]

2. Here \(z\) is defined as above. We assume \(\gamma \neq -w^{-1}(\theta)\) whenever both of the hypothesized edges are quantum ones. In the left diagram, the dashed edge is a quantum (resp. a Bruhat) edge depending on \(\langle w^{-1}(\theta), \gamma \rangle\) being nonzero (resp. zero). In the right diagram, the dashed edge is a Bruhat (resp. a quantum) edge depending on \(\langle w^{-1}(\theta), \gamma \rangle\) being nonzero (resp. zero).

   \[
   \begin{array}{ccc}
   \downarrow z(\gamma) & \xleftarrow{-[w_{\gamma}]^{-1}(\theta)} & \downarrow \gamma \\
   [r_\theta w_{\gamma}] & \xleftarrow{-[w_{\gamma}]^{-1}(\theta)} & [w_{\gamma}] \\
   \downarrow \gamma & & \downarrow \gamma \\
   [r_\theta w] & \xleftarrow{-[w_{\gamma}]^{-1}(\theta)} & [w_{\gamma}]
   \end{array}
   \]

3.3. Lifting \(QB(W^J)\) to the level-zero weight poset. In [Li], Littelmann introduced a poset related to LS paths for arbitrary (not necessarily dominant) integral weights. Littelmann did not give a precise local description of it. We consider this poset for level-zero weights and characterize its cover relations in terms of the PQBG.

Let \(\lambda \in X\) be a fixed dominant weight (cf. Section 2.2 and the notation thereof, e.g., \(W_J\) is the stabilizer of \(\lambda\)). We view \(X\) as a sublattice of \(X_{af}^0\). Let \(X_{af}^0(\lambda)\) be the orbit \(W_{af}\lambda\).
Theorem 3.4. Let $\mu \in X^0_{af}(\lambda)$ and $w := cl(\mu) \in W^J$. If $\mu < \nu$ is a cover in $X^0_{af}(\lambda)$, then its label $\beta$ is in $\Phi^+$ or $\delta - \Phi^+$. Moreover, $w \rightarrow cl(\nu)$ is an up (respectively down) edge in $QB(W^J)$ labeled by $w^{-1}(\beta) \in \Phi^+ \setminus \Phi^+_J$ (respectively $w^{-1}(\beta - \delta)$), depending on $\beta \in \Phi^+$ (respectively $\delta - \Phi^+$). Conversely, if $w \xrightarrow{\gamma} wr_\gamma = w'$ (respectively $w \xrightarrow{\gamma} [wr_\gamma] = w'$) in $QB(W^J)$ for $\gamma \in \Phi^+ \setminus \Phi^+_J$, then there exists a cover $\mu < \nu$ in $X^0_{af}(\lambda)$ labeled by $w(\gamma)$ (respectively $\delta + w(\gamma)$) with $cl(\nu) = w'$.

4. Models for KR crystals and the energy function

4.1. Quantum LS paths. Throughout this section, we fix a dominant integral weight $\lambda \in X$, and set $J := \{i \in I \mid \langle \alpha_i^\vee, \lambda \rangle = 0\}$.

Definition 4.1. Let $x, y \in W^J$, and let $\sigma \in \mathbb{Q}$ be such that $0 < \sigma < 1$. A directed $\sigma$-path from $x$ to $x$ is, by definition, a directed path

$$x = w_0 \xrightarrow{\gamma_1} w_1 \xrightarrow{\gamma_2} w_2 \xrightarrow{\gamma_3} \cdots \xrightarrow{\gamma_n} w_n = y$$

from $y$ to $x$ in $QB(W^J)$ such that $\sigma(\gamma_k^\vee, \lambda) \in \mathbb{Z}$ for all $1 \leq k \leq n$.

A quantum LS path of shape $\lambda$ is a pair $\eta = (x; \sigma)$ of a sequence $x : x_1, x_2, \ldots, x_s$ of elements in $W^J$ with $x_u \neq x_{u+1}$ for $1 \leq u \leq s - 1$ and a sequence $\sigma : 0 = \sigma_0 < \sigma_1 < \cdots < \sigma_s = 1$ of rational numbers such that there exists a directed $\sigma_u$-path from $x_{u+1}$ to $x_u$ for each $1 \leq u \leq s - 1$. Denote by $QLS(\lambda)$ the set of quantum LS paths of shape $\lambda$. We identify an element $\eta = (x_1, x_2, \ldots, x_s; \sigma_0, \sigma_1, \ldots, \sigma_s) \in QLS(\lambda)$ with the following piecewise linear, continuous map $\eta : [0, 1] \rightarrow \mathbb{R} \otimes \mathbb{Z} X$:

$$\eta(t) = \sum_{u'=1}^{u-1} (\sigma_{u'} - \sigma_{u'-1})x_{u'} \cdot \lambda + (t - \sigma_{u-1})x_u \cdot \lambda \quad \text{for} \quad \sigma_{u-1} \leq t \leq \sigma_u, \ 1 \leq u \leq s,$$

and set $wt(\eta) := \eta(1)$. Following [Li], we define the root operators $e_i$ and $f_i$ for $i \in I_{af} = I \sqcup \{0\}$ as follows. For $\eta \in QLS(\lambda)$ and $i \in I_{af}$, we set

$$H(t) = H^0_i(t) := \langle \alpha_i^\vee, \eta(t) \rangle \quad \text{for} \quad t \in [0, 1],$$

$$m = m_i^0 := \min\{H^0_i(t) \mid t \in [0, 1]\};$$

in fact, $m \in \mathbb{Z}_{\leq 0}$. If $m = 0$, then $e_i \eta := 0$. If $m \leq -1$, then we define $e_i \eta$ by:

$$(e_i \eta)(t) = \begin{cases} \eta(t) & \text{if } 0 \leq t \leq t_0, \\ r_{i, m+1}(t_0) + s_i(t) - \alpha_i & \text{if } t_0 \leq t \leq t_1, \\ r_{i, m+1}r_{i, m}(t) & \text{if } t_1 \leq t \leq 1, \end{cases}$$

where

$$t_1 := \min\{t \in [0, 1] \mid H(t) = m\},$$

$$t_0 := \max\{t \in [0, t_1] \mid H(t) = m + 1\},$$

and $s_i(t)$ is the integral part of $t$.
Theorem 4.2. The set \( QLS(\lambda) \) together with crystal operators \( e_i, f_i \) for \( i \in I_{af} \) and weight function \( wt \), becomes a regular crystal with weight lattice \( X \).

Remark 4.3. It is known that the fundamental representation \( W(\sigma) \) such that there exists a \( \nu \) such that there is a \( \alpha = \nu \) and \( \gamma \) such that \( \alpha + \gamma = 0 \). Furthermore, the crystal basis of \( \tilde{X}_0 \) (see also \( [NS3, Lemma 1.5.3] \)); we call it a (one-column) KR crystal. By the theorem above, the \( W(\sigma) \) to the KR module \( \sigma \) such that \( \nu = 0 \) and \( \gamma = 0 \). Corollary 4.5. For \( \lambda, \mu, \nu \in X(0) \) with \( \mu > \nu \) (see Definition 3.3) and a rational number \( 0 < \sigma < 1 \), a \( \sigma \)-chain for \( (\mu, \nu) \) is, by definition, a sequence \( \mu = \xi_0 > \xi_1 > \cdots > \xi_n = \nu \) of covers in \( X(0) \) such that \( \sigma(\xi_k) \), \( \xi_k \in \mathbb{Z} \) for all \( k = 1, 2, \ldots, n \), where \( \xi_k \) is the label for \( \xi_k \).

Definition 4.4. For \( \lambda, \nu \in X(0) \) with \( \mu > \nu \) (see Definition 3.3) and a rational number \( 0 < \sigma < 1 \), a \( \sigma \)-chain for \( (\mu, \nu) \) is, by definition, a sequence \( \mu = \xi_0 > \xi_1 > \cdots > \xi_n = \nu \) of covers in \( X(0) \) such that \( \sigma(\xi_k) \), \( \xi_k \in \mathbb{Z} \) for all \( k = 1, 2, \ldots, n \), where \( \xi_k \) is the label for \( \xi_k \).

Definition 4.5. An LS path of shape \( \lambda \) is, by definition, a pair \( (\nu; \sigma) \) of a sequence \( \nu : \nu_1 > \nu_2 > \cdots > \nu_s \) of elements in \( X(0) \) (and a sequence \( \sigma : 0 = \sigma_0 < \sigma_1 < \cdots < \sigma_s = 1 \) of rational numbers such that there exists a \( \sigma \)-chain for \( (\nu_0, \nu_{s+1}) \) for each \( u = 1, 2, \ldots, s - 1 \).

We denote by \( \mathbb{B}(\lambda) \) the set of all LS paths of shape \( \lambda \). We identify an element

\[
\pi = (\nu_1, \nu_2, \ldots, \nu_s; \sigma_0, \sigma_1, \ldots, \sigma_s) \in \mathbb{B}(\lambda)
\]

with the following piecewise linear, continuous map \( \eta : [0, 1] \to \mathbb{R} \otimes X(0) \):

\[
\eta(t) = \sum_{u'=1}^{u-1} (\sigma_{u'} - \sigma_{u'-1}) \nu_u + (t - \sigma_{u-1}) \nu_u \quad \text{for} \quad \sigma_{u-1} \leq t \leq \sigma_u, \quad 1 \leq u \leq s.
\]
Let $\mathcal{B}(\lambda)_{cl} := \{ cl(\pi) : \pi \in \mathcal{B}(\lambda) \}$, where $cl(\pi)$ is the piecewise linear, continuous map $[0, 1] \to \mathbb{R} \otimes \mathbb{Z} \times$ defined by $(cl(\pi))(t) := cl(\pi(t))$ for $t \in [0, 1]$. For $\eta \in \mathcal{B}(\lambda)_{cl}$ and $i \in I_{af}$, we define $e_i \eta$ and $f_i \eta$ in exactly the same way as above. Then it is known from [NS1, NS2] that the same statement as in Theorem 4.2 holds for $\mathcal{B}(\lambda)_{cl}$. Thus, Theorem 4.2 follows immediately from the following proposition.

**Proposition 4.6.** The affine crystals $QLS(\lambda)$ and $\mathcal{B}(\lambda)_{cl}$ are isomorphic.

This proposition is a consequence of Theorem 3.4. Let us show that if $\eta \in QLS(\lambda)$, then $\eta \in \mathcal{B}(\lambda)_{cl}$. Here, for simplicity, we assume that $\eta = (x, y; 0, \sigma, 1) \in QLS(\lambda)$, and $x = w_0 \overset{\gamma_1}{\leftarrow} w_1 \overset{\gamma_2}{\leftarrow} w_2 = y$ is a directed $\sigma$-path from $y$ to $x$. Take an arbitrary $\mu \in X^0_{af}(\lambda)$ such that $cl(\mu) = y$.

By applying Theorem 3.4 to $w_1 \overset{\gamma_2}{\leftarrow} w_2 = y$, we obtain a cover $\nu_1 > \mu$ for some $\nu_1 \in X^0_{af}(\lambda)$ with $cl(\nu_1) = w_1$. Then, by applying Theorem 3.4 to $x = w_0 \overset{\gamma_1}{\leftarrow} w_1$, we obtain a cover $\nu > \nu_1$ for some $\nu \in X^0_{af}(\lambda)$ with $cl(\nu) = x$. Thus we get a sequence $\nu > \nu_1 > \mu$ of covers in $X^0_{af}(\lambda)$. It can be easily seen that this is a $\sigma$-chain for $(\nu, \mu)$, which implies that $\pi = (\nu, \mu; 0, \sigma, 1) \in \mathcal{B}(\lambda)$. Therefore, $\eta = cl(\pi) \in \mathcal{B}(\lambda)_{cl}$. The reverse inclusion can be shown similarly.

### 4.3. Description of the energy function in terms of quantum LS paths

Recall the notation in Theorem 4.2 (2): for simplicity, we set $\lambda := \lambda_1$. In [NS5], Naito and Sagaki introduced a degree function $Deg_\lambda : \mathcal{B}(\lambda)_{cl} = QLS(\lambda) \to \mathbb{Z}_{\leq 0}$, and proved that $Deg_\lambda$ is identical to the energy function [HKOTT, HKOTY] on the tensor product $\mathcal{B}(\lambda)_{cl} \otimes \mathcal{B}(\lambda)_{cl} \otimes \cdots \otimes \mathcal{B}(\lambda)_{cl} = QLS(\lambda_1) \otimes QLS(\lambda_2) \otimes \cdots \otimes QLS(\lambda_s)$ (which is isomorphic to the corresponding tensor product of KR crystals; see Remark 4.3) via the isomorphism $W_I$. The function $Deg_\lambda : \mathcal{B}(\lambda)_{cl} \to \mathbb{Z}_{\leq 0}$ is described in terms of $QB(W_J)$ as follows. For $x, y \in W_J$ let

$$d : x = w_0 \overset{\beta_1}{\leftarrow} w_1 \overset{\beta_2}{\leftarrow} \cdots \overset{\beta_n}{\leftarrow} w_n = y$$

be a shortest directed path from $y$ to $x$, and define

$$\text{wt}(d) := \sum_{1 \leq k \leq n \text{ such that } w_{k-1} \overset{\beta_k}{\leftarrow} w_k \text{ is a down arrow}} \beta_k^\vee.$$

The value $(\text{wt}(d), \lambda)$ does not depend on the choice of a shortest directed path $d$ from $y$ to $x$, and

**Theorem 4.7.** Let $\eta = (x_1, x_2, \ldots, x_s; \sigma_0, \sigma_1, \ldots, \sigma_s) \in QLS(\lambda) = \mathcal{B}(\lambda)_{cl}$. Then,

$$(6) \quad \text{Deg}(\eta) = -\sum_{u=1}^{s-1} (1 - \sigma_u) \langle \lambda, \text{wt}(d_u) \rangle,$$

where $d_u$ is a shortest directed path from $x_{u+1}$ to $x_u$.

### 4.4. The quantum alcove model

The quantum alcove model is a generalization of the alcove model of the first author and Postnikov [LP1, LP2], which, in turn, is a discrete counterpart of the Littelmann path model [Li]. For the affine Weyl group terminology below, we refer to [H]. Fix a dominant weight $\lambda$. We say that two alcoves are adjacent if they are distinct and have a common wall. Given a pair of adjacent alcoves $A$ and $B$, we write $A \rightarrow B$ for $\beta \in \Phi$ if the common wall is orthogonal to $\beta$ and $\beta$ points in the direction from $A$ to $B$.

**Definition 4.8.** [LP1] The sequence of roots $(\beta_1, \beta_2, \ldots, \beta_m)$ is called a $\lambda$-chain if

$$A_0 = A_0 \rightarrow -\beta_1 \rightarrow A_1 \rightarrow -\beta_2 \rightarrow \cdots \rightarrow -\beta_m \rightarrow A_m = A_0 - \lambda$$

is a shortest sequence of alcoves from the fundamental alcove $A_0$ to its translation by $-\lambda$. 
Thus, we have proved that \( A \) crystal, cf. [FSS]. Moreover the above bijection sends the level statistic to the Deg statistic of (6).

Demazure arrows (7) polynomials associated to any affine root system (where \( \lambda \) is the stabilizer of \( \lambda \) in \( W \), thereby obtaining a quantum LS path. The inverse map is more subtle, and is based on the so-called tilted Bruhat theorem of [LNSS1]; this is a QBG analogue of the minimum-length Deodhar lift [De] \( W/W_{\lambda} \to W \).

An affine crystal structure was defined on \( A \) (possibly empty) finite subset \( J = \{ j_1 < j_2 < \cdots < j_s \} \) of \( \{ 1, \ldots, m \} \) is a \( \Gamma \)-admissible subset if we have the following path in QB(W):

\[
1 \overset{\beta_{j_1}}{\longrightarrow} r_{j_1} \overset{\beta_{j_2}}{\longrightarrow} r_{j_1}r_{j_2} \overset{\beta_{j_3}}{\longrightarrow} \cdots \overset{\beta_{j_s}}{\longrightarrow} r_{j_1}r_{j_2} \cdots r_{j_s} = \kappa(J).
\]

Let \( A^\Gamma(\lambda) \) be the collection of \( \Gamma \)-admissible subsets. Define the level of \( J \in A^\Gamma(\lambda) \) by level(\( J \)) = \( \sum_{j \in J} -l_j \), where \( J^- \subseteq J \) corresponds to the down steps in Bruhat order in (7).

**Theorem 4.10.** There is an isomorphism of graded classical crystals \( \Xi : A^{\Gamma_{\text{lex}}}(\lambda) \to \text{QLS}(\lambda) \).

The map \( \Xi \) is the following forgetful map. Given the path (7), based on the structure of \( \Gamma_{\text{lex}} \) we select a subpath, and project its elements under \( W \to W/W_{\lambda} \) where \( W_{\lambda} \) is the stabilizer of \( \lambda \) in \( W \), thereby obtaining a quantum LS path. The inverse map is more subtle, and is based on the so-called tilted Bruhat theorem of [LNSS1]; this is a QBG analogue of the minimum-length Deodhar lift [De] \( W/W_{\lambda} \to W \).

In [LeL2], we show that all the affine crystals \( A^\Gamma(\lambda) \), for various \( \Gamma \), are isomorphic. Making particular choices in classical types, we can translate the level statistic into a so-called charge statistic on sequences of the corresponding Kashiwara–Nakashima columns [KN]. In type \( A \), we recover the classical Lascoux–Schützenberger charge [LSc]. Type \( C \) was worked out in [Le2, LeS], while type \( B \) is considered in [BL].

## 5. Macdonald Polynomials

The symmetric Macdonald polynomials \( P_\lambda(x; q, t) \) [M] are a remarkable family of orthogonal polynomials associated to any affine root system (where \( \lambda \) is a dominant weight for the canonical finite root system), which depend on parameters \( q, t \). They generalize the corresponding irreducible characters, which are recovered upon setting \( q = t = 0 \). For untwisted affine root systems the Ram–Yip formula [RY] expresses \( P_\lambda(x; q, t) \) in terms of all subsequences of any \( \lambda \)-chain \( \Gamma \) (cf. Definition 4.8). In [Le2], it was shown that the Ram–Yip formula takes the following simple form for \( t = 0 \):

\[
P_\lambda(x; q, 0) = \sum_{J \in A^\Gamma(\lambda)} q^{\text{level}(J)} x^{\text{wt}(J)},
\]

where \( \text{wt}(J) \) is a weight associated with \( J \). By using the results in Section 4.4, we can write the right-hand side of (8) as a sum over the corresponding tensor product of KR crystals. It follows that \( P_\lambda(x; q, 0) = X_\lambda(q) \). Furthermore, we can express the nonsymmetric Macdonald polynomial \( E_{w\lambda}(x; q, 0) \), for \( w \in W \), in a similar way to (8), by summing over those \( J \in A^\Gamma(\lambda) \) with \( \kappa(J) \leq w \) (in Bruhat order), where \( \kappa(J) \) was defined in (7). This formula can be derived both by induction, based on Demazure operators, and from the Ram–Yip formula (in this case, for nonsymmetric Macdonald polynomials); however, the latter derivation is more involved than the one of (8), as it uses the transformation on admissible subsets defined in [Le1, Section 5.1].
